BIOCHEMISTRY AND GENETICS OF COMPLEMENT

Complement is an essential feature of an animal's ability to develop immunity to infection. This volume summarizes present understanding of this complex system in terms of the structures of the protein components and their activation mechanisms.

The papers, which were presented at a Discussion Meeting on 25 and 26 January 1984, describe the genetics of these proteins, together with recent contributions by recombinant DNA techniques to the organization of the genes of the three complement components that are present in the major histocompatibility complex.
